

What is wavelength-division multiplexing (WDM)?

Due to the lower data rate of the IM-DD system for a single wavelength channel than the coherent scheme, wavelength-division multiplexing (WDM) technology is commonly employed to economically enhance the data capacity.

## What is Multiplexing using WDM?

The following diagram conceptually represents multiplexing using WDM. It has 4 optical signals having 4 different wavelengths. Each of the four senders generates data streams of a particular wavelength. The optical combinermultiplexes the signals and transmits them over a single long-haul fiber channel.

## How does a WDM optical communication system work?

In a WDM optical communication system, multiple data channels carried by optical beams with different wavelengths are multiplexed at the transmitter. They can be simultaneously transmitted through the link and de-multiplexed at the receiver.

## What is multiplexing in satellite communications?

Satellite Communications: Multiplexing helps in efficiently utilizing the available bandwidth on satellite transponders, allowing multiple signals to be transmitted and received simultaneously. The below are the different types of multiplexing techniques, each designed to handle various types of data and communication needs.

### How are WDM mid IR channels converted to IR OAM beams?

The WDM mid-IR channels are generated in the C-band and wavelength converted to the mid-IR. The mid-IR Gaussian beams are converted to mid-IR OAM beams by passing them through spiral phase plates(SPPs). Fig. 1.
